

What I understand of generative AI and how it works is that to create an output, it must study existing examples. Therefore, those who use generative AI must firstly train their generative AI model using an image set they wish for it to learn from. In a process very reminiscent of machine learning, the generative AI model will analyze these images to learn how they are made. It will create categories (face, elbow, shoulder, etc...) and assign elements it recognizes from the images in these categories. Finally, now that it understands what an illustration is made of, to produce images, it will put together the various elements it was taught to understand as an illustration of a subject of your choice in the format of an “original“ output made by taking and combining the many landmarks it studied beforehand.

From what I’ve seen and experienced, generative AI’s application in creative fields mostly consists in creating assets and editing existing assets.

For creating assets, generative AI can create multiple kinds of images for different kinds of creative needs. Generative AI can create pictures, paintings & drawings, 3D models, noise maps, height maps, and more. When generating such output, however, generative AI has a tendency towards errors and creating visual artifacts. It is usually a combination of many small errors that it can accidentally produce when generating output that when combined affect the overall result such as poor resolution, blurry images, lack of logic when depicting certain complicated elements (chains & necklaces, faces), lack of connection/continuity between connected objects (two different faces of a same building).

For editing existing assets, generative AI can perform video and image manipulation. It can increase the framerate of a video through interpolation, it can add and remove people in a photo, it can change or dynamically modify the background of a photo/video and it can also change the poses of people in a photo and change the actions people take in a video. Just like when creating assets, when editing existing assets generative AI can still make the same mistakes as the ones explained before. Which is why supervision combined with verifying the output is important.

One work of generative AI-driven art that I find inspiring is WAVE. Wave is a dance video published by Youtuber Masaki Mizuno featuring transforming background graphics handled by a generative AI model. The video’s backgrounds shift, ripple

and bend in interesting ways in a motion graphics-esque manner all thanks to a generative AI-model transforming the background.

This work is inspiring to me because it creatively takes advantage of the errors and general weirdness of the output of generative AI. “Noise” and “hallucination” are the driving concepts behind this video project. Using generative AI to, in their words, “deliberately induce hallucination”. As seen through the kaleidoscopic and hypnotizing transformations of the backgrounds enhanced by the mistakes and artifacts created by generative AI. I believe that one of the most interesting ways of making use of generative AI in creative work is taking advantage of the weirdness of its output
